

# Workshop #5

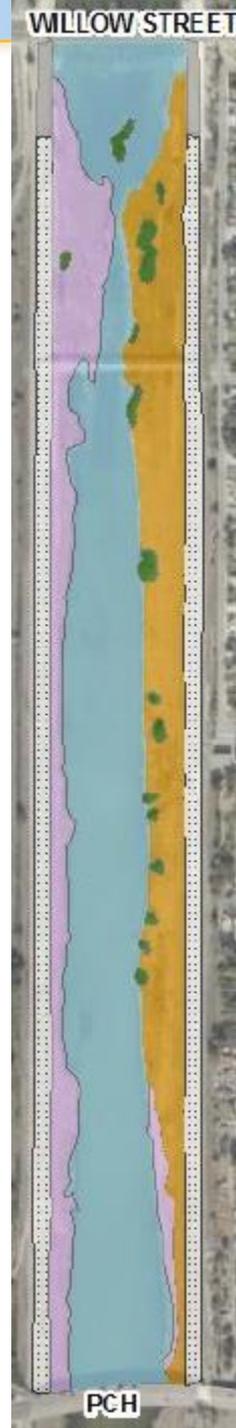

July 23, 2015

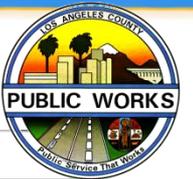

## Reach 25 – Lower LA River

### No-maintenance Condition

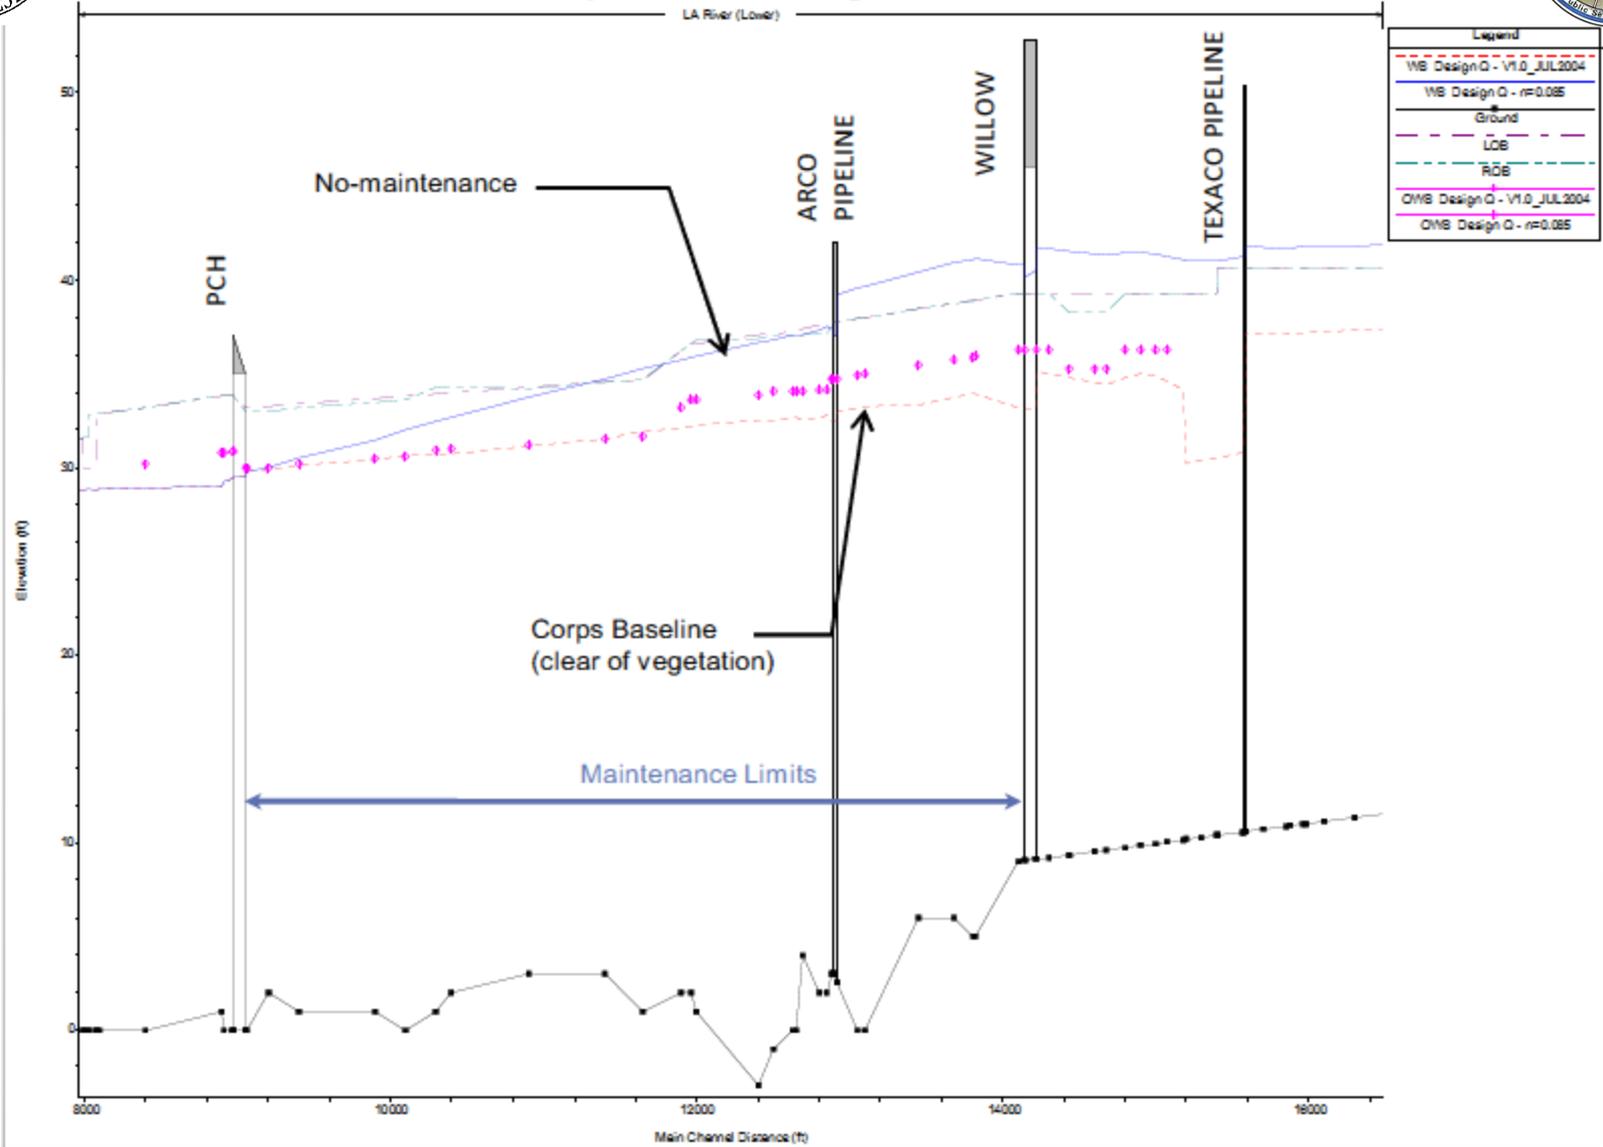

- Allow natural growth of all vegetation

# Reach 25 – Lower LA River

LACDA - Stormwater Management Plan Plan: 1) V1.0\_JUL2004 4/15/2015 2) n=0.085 8/1/2015

# Levee Overtopping

# Manning's Roughness Coefficient

# Manning's Roughness Coefficient

- Very significant in computing water surface profiles
- Estimated using formula developed by Cowan (1956)

$$n = (n_b + n_1 + n_2 + n_3 + n_4)m$$

*Where:*

$n_b$  = a base value of  $n$  for a straight, uniform, smooth channel in natural materials,

$n_1$  = a correction factor for the effect of surface irregularities,

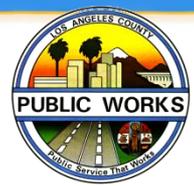

$n_2$  = a value for variation in the shape and size of the channel cross section,

$n_3$  = a value for obstructions,

$n_4$  = a value for vegetation and flow conditions, and

$m$  = a correction factor for meandering of the channel

- Adjustments based on field site observations

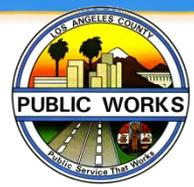

# Selection of Base Values of Manning's $n$

**Table 1.** Base values of Manning's  $n$   
 [Modified from Aldridge and Garrett, 1973, table 1; —, no data]

| Bed material                     | Median size of bed material (in millimeters) | Base $n$ value                        |                             |
|----------------------------------|----------------------------------------------|---------------------------------------|-----------------------------|
|                                  |                                              | Straight uniform channel <sup>1</sup> | Smooth channel <sup>2</sup> |
| Sand channels                    |                                              |                                       |                             |
| Sand <sup>3</sup> .....          | 0.2                                          | 0.012                                 | —                           |
|                                  | .3                                           | .017                                  | —                           |
|                                  | .4                                           | .020                                  | —                           |
|                                  | .5                                           | .022                                  | —                           |
|                                  | .6                                           | .023                                  | —                           |
|                                  | .8                                           | .025                                  | —                           |

# Selection of Adjustment Factor for Vegetation

| Amount of vegetation ( $n_4$ ) | Adjustment Factor | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Small                          | 0.002–0.010       | Dense growths of flexible turf grass, such as Bermuda, or weeds growing where the average depth of flow is at least two times the height of the vegetation; supple tree seedlings such as willow, cottonwood, arrowweed, or saltcedar growing where the average depth of flow is at least three times the height of the vegetation.                                                                                                                                                                          |
| Medium                         | 0.010–0.025       | Turf grass growing where the average depth of flow is from one to two times the height of the vegetation; moderately dense stemmy grass, weeds, or tree seedlings growing where the average depth of flow is from two to three times the height of the vegetation; brushy, moderately dense vegetation, similar to 1- to 2-year-old willow trees in the dormant season, growing along the banks, and no significant vegetation is evident along the channel bottoms where the hydraulic radius exceeds 2 ft. |
| Large                          | 0.025–0.050       | Turf grass growing where the average depth of flow is about equal to the height of the vegetation; 8- to 10-year-old willow or cottonwood trees intergrown with some weeds and brush (none of the vegetation in foliage) where the hydraulic radius exceeds 2 ft; bushy willows about 1 year old intergrown with some weeds along side slopes (all vegetation in full foliage), and no significant vegetation exists along channel bottoms where the hydraulic radius is greater than 2 ft.                  |
| Very large                     | 0.050–0.100       | Turf grass growing where the average depth of flow is less than half the height of the vegetation; bushy willow trees about 1 year old intergrown with weeds along side slopes (all vegetation in full foliage), or dense cattails growing along channel bottom; trees intergrown with weeds and brush (all vegetation in full foliage).                                                                                                                                                                     |

# Manning's Roughness Coefficient

- Adjustment factors range depending on channel conditions
- Depth of flow must be considered
- Adjustment factors are picked from a table, not calculated
- Channel conditions for each reach were discussed and compared

**Cattails, small shrubs**

$n_b = 0.025$  (firm soil)  
 $n_4$  (vegetation) = 0.010 (med)  
 **$n = 0.035$**

**Open Water**

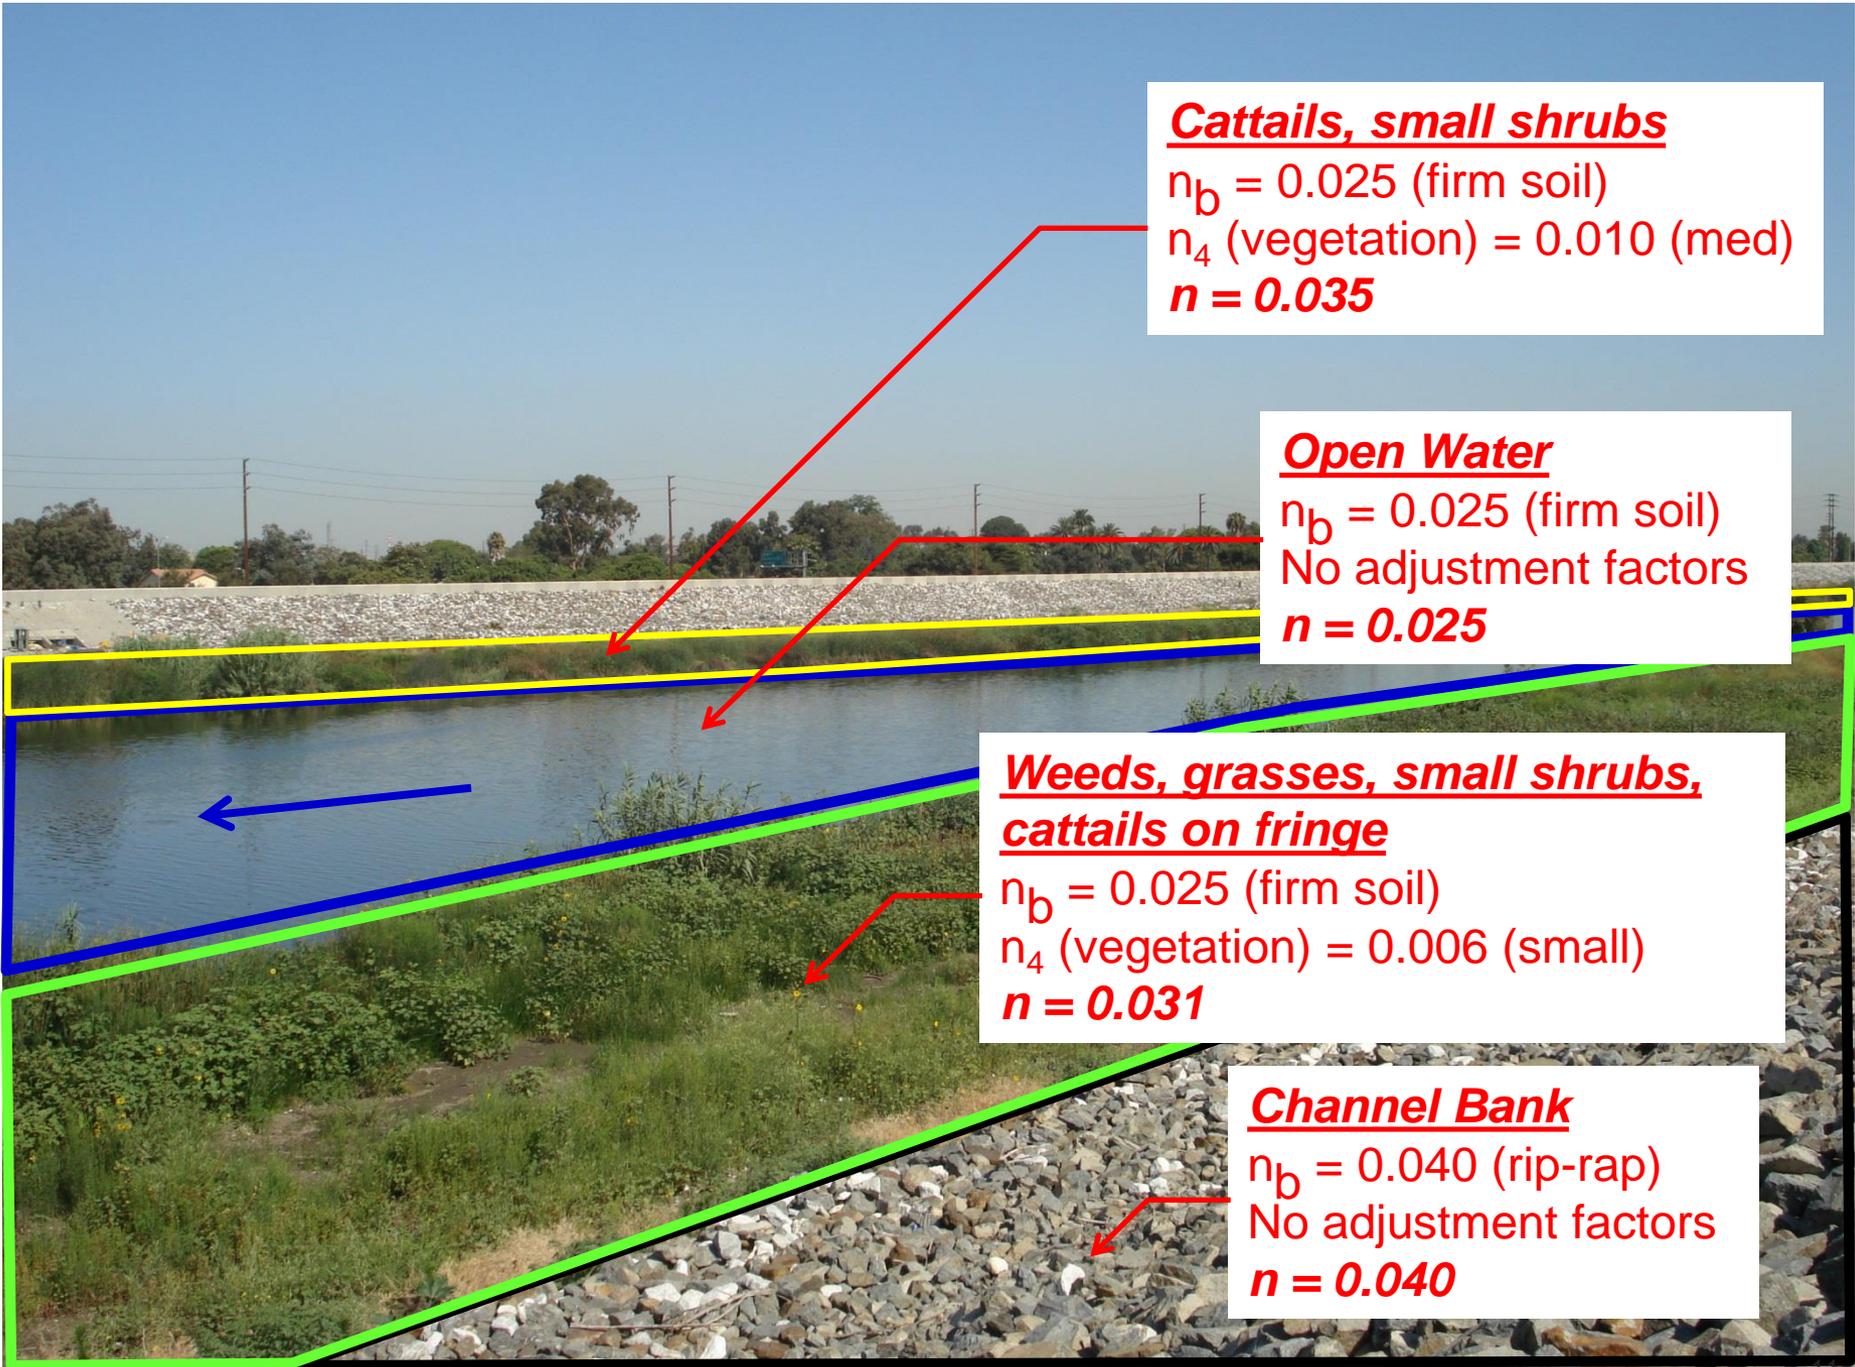

$n_b = 0.025$  (firm soil)  
No adjustment factors  
 **$n = 0.025$**

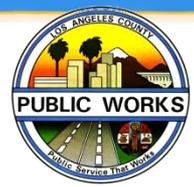

**Weeds, grasses, small shrubs,  
cattails on fringe**

$n_b = 0.025$  (firm soil)  
 $n_4$  (vegetation) = 0.006 (small)  
 **$n = 0.031$**

**Channel Bank**

$n_b = 0.040$  (rip-rap)  
No adjustment factors  
 **$n = 0.040$**

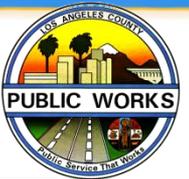

# Reach 25 – Lower LA River

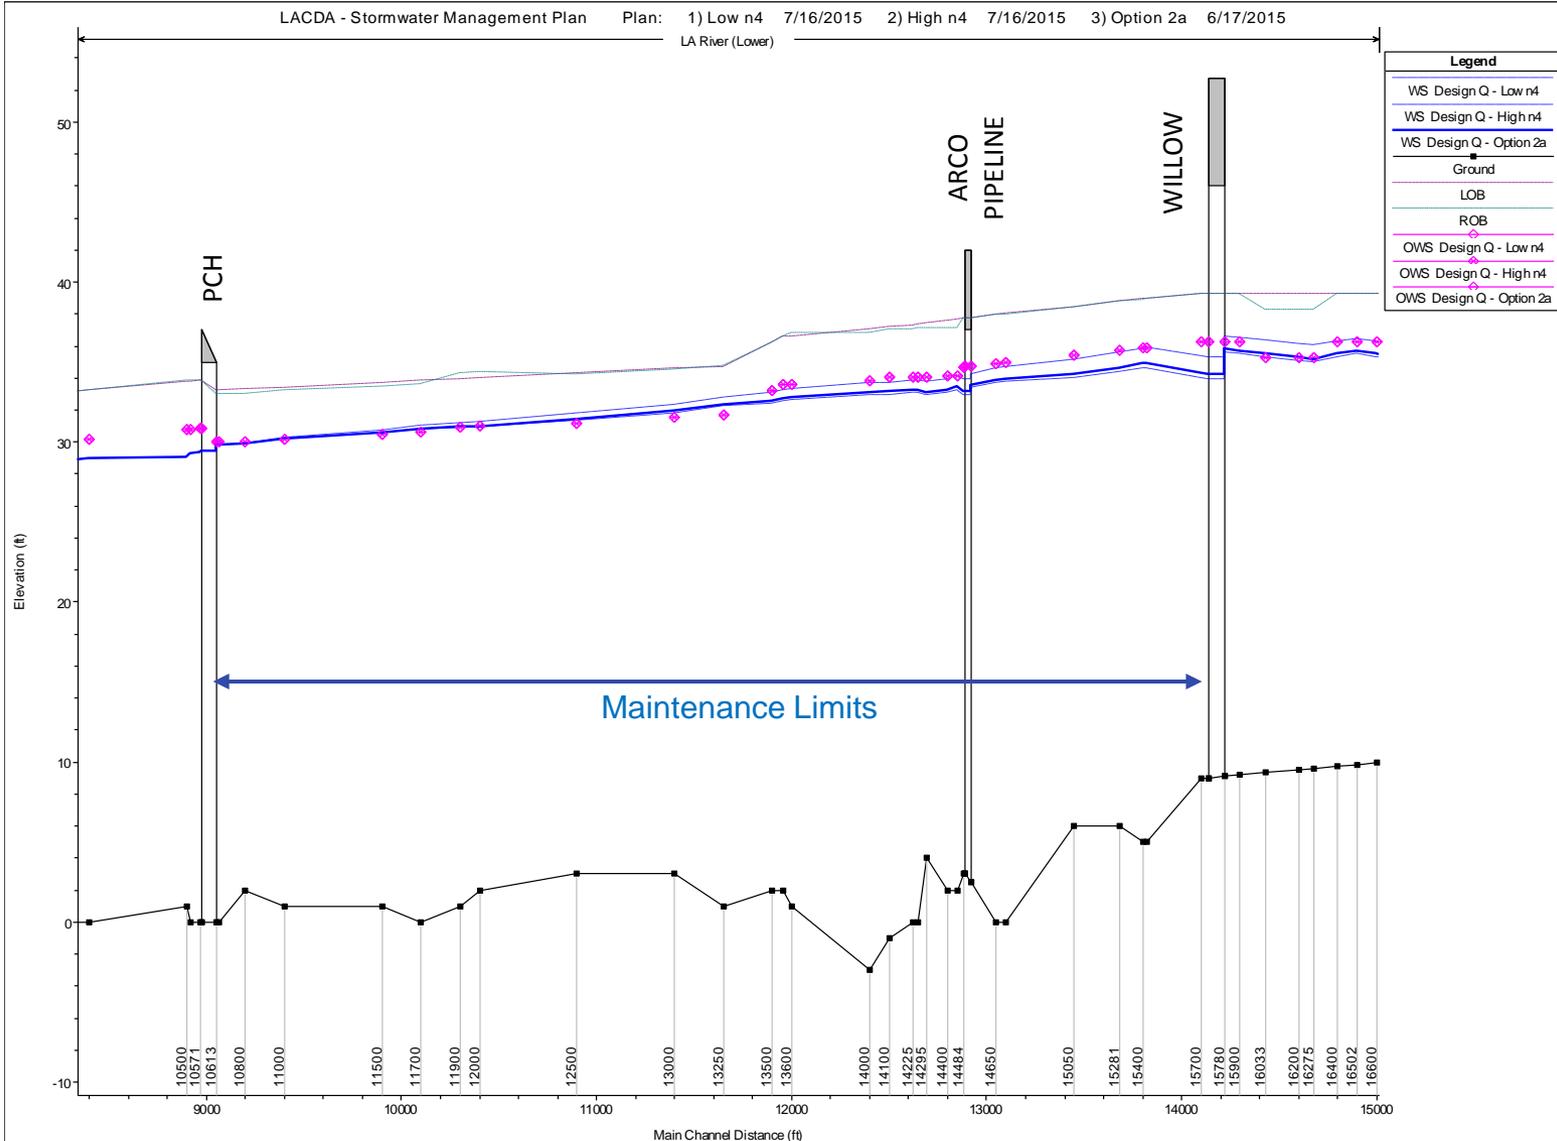

## Summary of Roughness Coefficients

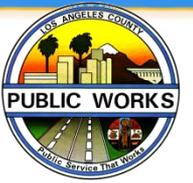

| Description                                                | $n_b$         |               |               |                  |             | $n_4$         |               |               |               | Low Range | Total "n" | High Range |
|------------------------------------------------------------|---------------|---------------|---------------|------------------|-------------|---------------|---------------|---------------|---------------|-----------|-----------|------------|
|                                                            | Base "n"      |               |               |                  |             | Vegetation    |               |               |               |           |           |            |
|                                                            | 0.026 – 0.035 | 0.025 – 0.032 | 0.024 – 0.035 | 0.012 – 0.018    | 0.03 – 0.07 | 0.002 – 0.010 | 0.010 – 0.025 | 0.025 – 0.050 | 0.050 – 0.100 |           |           |            |
| Sand                                                       | Firm Soil     | Gravel        | Concrete      | Cobble / Boulder | Small       | Medium        | Large         | Very Large    |               |           |           |            |
